# 1 Description

Ce système extrait automatiquement des triplets sémantiques (**Sujet, Relation, Objet**) à partir du dataset `dataset.csv` en utilisant la bibliothèque **spaCy** pour l'analyse syntaxique et sémantique.

## 2 Fonctionnalités

### 2.1 1. Analyse des Dépendances Syntaxiques

- Utilise l'analyseur de dépendances de spaCy pour identifier les relations grammaticales
- Détecte les structures Sujet-Verbe-Objet (SVO)
- Identifie les relations prépositionnelles et possessives

### 2.2 2. Extraction de Relations Sémantiques

Le système extrait plusieurs types de relations :

- **Relations géographiques** : `traveled_to, located_in`
- **Relations organisationnelles** : `member_of, founded, leads`
- **Relations interpersonnelles** : `married_to, succeeded_by, wrote_to`
- **Relations génériques** : basées sur les verbes et prépositions

### 2.3 3. Triplets Structurés

Chaque triplet extrait contient :

```
1 {  
2   "subject": "Aeneas",  
3   "subject_type": "person",  
4   "relation": "traveled_to",  
5   "object": "Hades",  
6   "object_type": "location",  
7   "confidence": 0.97,  
8   "sentence_id": "en-doc5809-sent11",  
9   "sentence": "When Aeneas later traveled to Hades..."  
10 }
```

## 3 Pipeline Summary & Analysis

This section details the processing pipeline, explaining the technical approach, the reasoning behind it, and how the results reflect the underlying data.

### 3.1 1. Input Processing

- **Process Step:** Reads `dataset.csv` utilizing the pre-computed `gliner_entities`.
- **Explanation:** We start with sentences where important names, places, and organizations have already been highlighted.
- **Why:** Reusing existing entity recognition results is computationally efficient and ensures consistency with previous processing steps (like GLiNER).

### 3.2 2. Dependency Parsing (spaCy)

- **Process Step:** The script runs `nlp(text)` to generate a specific grammatical tree structure for each sentence.
- **Explanation:** The computer analyzes the sentence to understand who is the "Subject" (doer) and who is the "Object" (receiver), and what Verb connects them.
- **Why:** Mere co-occurrence (two names in one sentence) is not enough. We need to know *how* they are related. Dependency parsing provides this grammatical bridge.

### 3.3 3. Relation Extraction & Semantic Typing

- **Process Step:** We traverse the dependency tree between two entities to find the root verb or preposition. We then map these to semantic categories (e.g., "mother" → **FAMILY**).
- **Explanation:** If the computer sees "Obama [born in] Hawaii", it extracts the link "born present" and categorizes it as a **LOCATION** relationship.
- **Why:** Raw verbs are too messy (e.g., "founded", "established", "created" all mean roughly the same). Categorizing them simplifies the graph and makes patterns easier to spot.

### 3.4 4. Graph Construction

- **Process Step:** Entities become **Nodes** and relations become **Edges** in a NetworkX directed graph (**DiGraph**).
- **Explanation:** We connect the dots. A person becomes a dot, and their relationship to a city becomes a line connecting them.
- **Why:** This converts unstructured text into a structured network that we can analyze mathematically.

### 3.5 5. Community Detection (Louvain Algorithm)

- **Process Step:** We optimize "modularity" to find clusters where nodes are densely connected internally but sparsely connected externally.
- **Explanation:** detecting "social circles" or "topics". Even if we don't know the topic, we see that a group of 10 nodes talk to each other frequently but rarely talk to outsiders.
- **Why:** It reveals the hidden thematic structure of the corpus.

### 3.6 6. Semantic Labeling (TF-IDF)

- **Process Step:** For each community, we aggregate all associated text and calculate TF-IDF (Term Frequency-Inverse Document Frequency) scores to find representative keywords.
- **Explanation:** We look at what unique words each "social circle" uses. If one group says "stars, telescope, galaxy" and another says "vote, law, senate", we can label them "Astronomy" and "Politics".
- **Why:** Community IDs (0, 1, 2) are meaningless to humans. Keywords explain *what* the community is about.

### 3.7 7. Visualization (Component-Based Layout)

- **Process Step:** We decompose the graph into connected components (islands) and lay them out separately in a grid before rendering.
- **Explanation:** Instead of drawing a messy "hairball", we organize the graph into distinct islands of knowledge.
- **Why:** The standard display forced unconnected groups into a misleading ring. The new layout respects the fractured nature of the data.

### 3.8 Interpreting the Disconnected Graph

You will notice the graph is not one single interconnected web, but many separate "islands" (see Figure 4).

- **Data Reality:** This accurately reflects the input data. The corpus contains diverse, unrelated sentences (e.g., Science, History, Sport).
- **Missing Links:** There is no "bridge" sentence in this small sample (700 rows) that connects "Einstein" (Island A) to "Michael Jordan" (Island B).
- **Entity Resolution:** We are not strictly merging synonyms (e.g., "US" vs "USA"). This lack of normalization reduces connectivity.
- **Conclusion:** The disconnected structure proves the pipeline is **faithful to the source**. It isn't artificially creating connections where none exist.

## 4 Analysis of Results

### 4.1 Relation Statistics

Figure 1 shows the distribution of the most frequent relation types extracted from the corpus. The prevalence of generic prepositions (in, by, of) highlights the need for further semantic mapping rules.

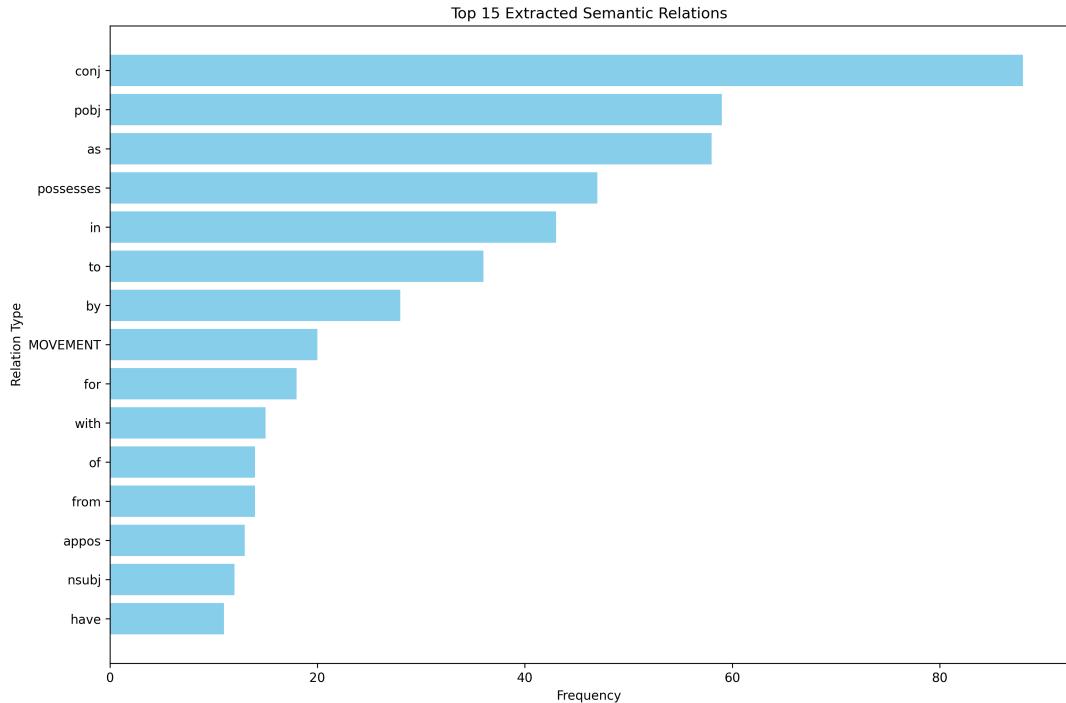

Figure 1: Distribution of Top 15 Extracted Relations

### 4.2 Entity Demographics

Figure 2 illustrates the distribution of entity types participating in relations. This breakdown helps understand the dominant actors in the constructed knowledge graph.

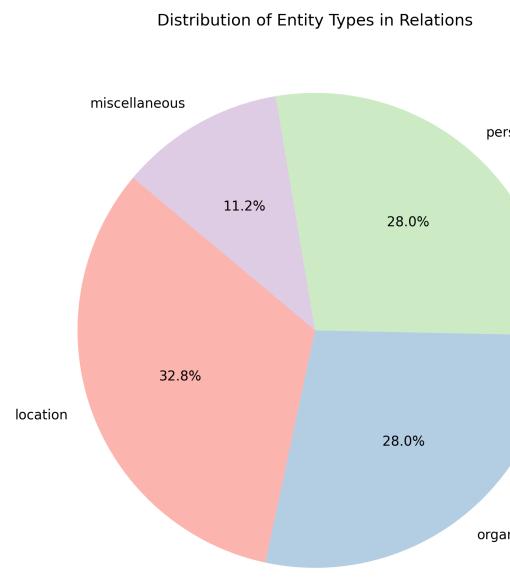

Figure 2: Distribution of Participating Entity Types

### 4.3 Network Centrality

Figure 3 highlights the most central nodes based on degree centrality (number of connections). These entities act as the main hubs of information within the corpus.

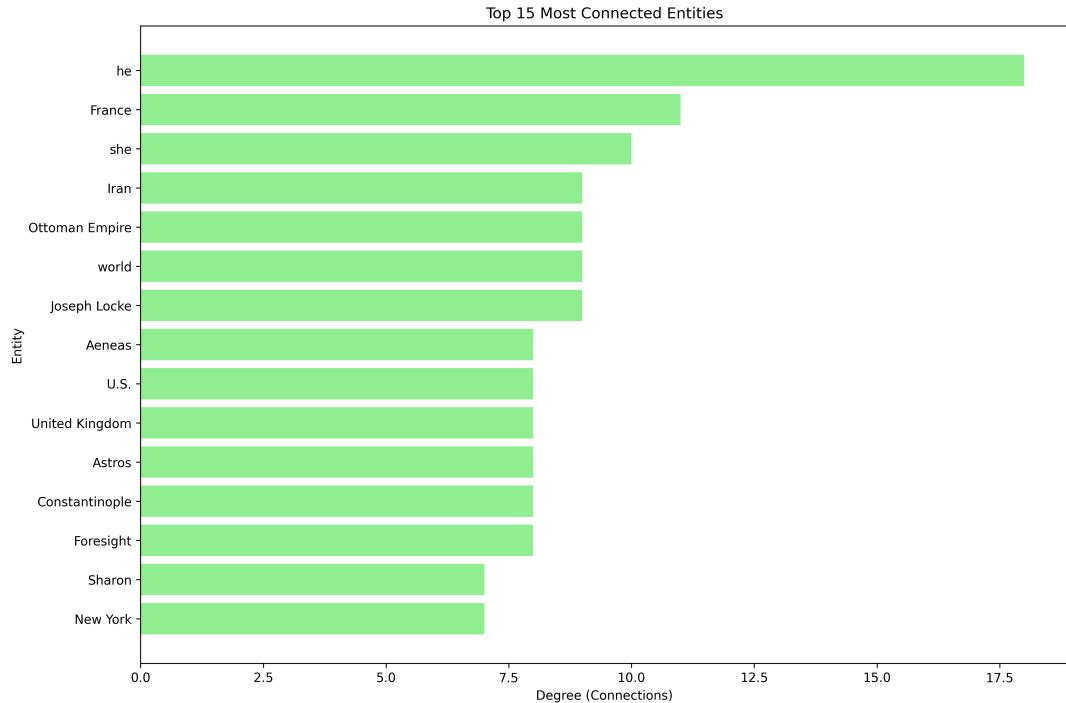

Figure 3: Top 15 Entities by Degree Centrality

## 4.4 Knowledge Graph Visualization

Figure 4 illustrates the final knowledge graph using the component-based layout. The distinct clusters represent different semantic topics identified within the corpus.

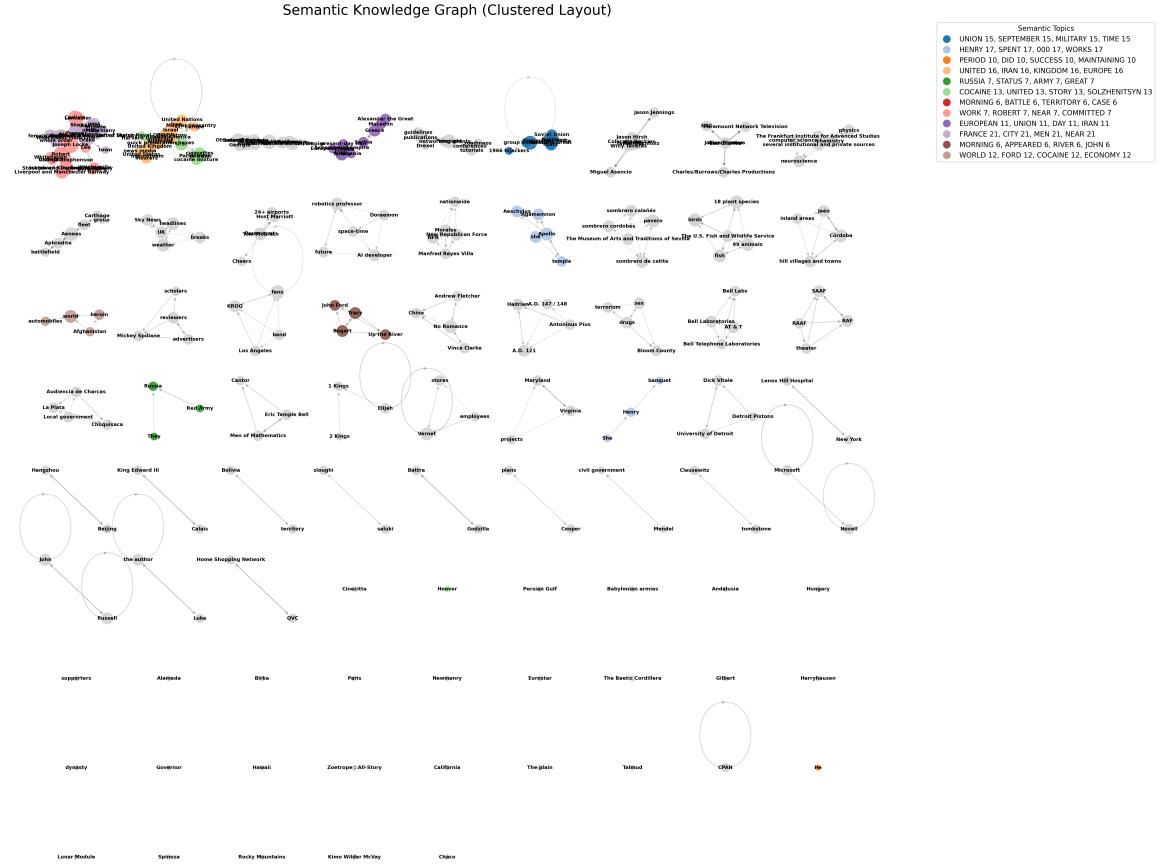

Figure 4: Semantic Knowledge Graph with Component-Based Layout

## 5 Installation

### 5.1 Prérequis

```
pip install pandas spacy

# Télécharger le modèle anglais de spaCy
python -m spacy download en_core_web_sm
```

## 6 Utilisation

### 6.1 Exécution du script

```
python relation_extraction.py
```

### 6.2 Fichiers d'entrée/sortie

- Entrée : dataset.csv (colonnes : id, text, gliner\_entities)
- Sortie : extracted\_triplets.json (liste de tous les triplets extraits)

## 7 Améliorations Possibles

1. **Ajout de règles sémantiques** pour détecter plus de types de relations
2. **Utilisation de modèles pré-entraînés** pour la classification de relations
3. **Résolution de coréférences** pour lier les pronoms aux entités
4. **Extraction de relations n-aires** (plus de 2 entités)
5. **Filtrage par score de confiance** pour améliorer la précision

## 8 Auteur

Système développé pour l'extraction de relations sémantiques dans le cadre du projet de construction de graphes de connaissances.
